

Anatomy of the subset() command for splitting data by group

In words: “Make a new R object using the subset command by taking the salmon dataframe, selecting the brook.trout.PRES.ABS and percent.surv columns, and returning just the rows of data where brook.trout.PRES.ABS contains the word “present.”

Subsetting data with subset()

1)Original dataframe

```
> salmon
```

	brook.trout.PRES.ABS	salmon.released	salmon.surv
1	present	820	166
2	present	960	136
3	present	700	153
4	present	545	103
5	present	769	173
6	present	1001	188
7	absent	467	180
8	absent	959	178
9	absent	1029	326
10	absent	27	7
11	absent	998	120
12	absent	936	135

```
present <- subset(salmon,  
  select = c("brook.trout.PRES.ABS",  
    "percent.surv"),  
  brook.trout.PRES.ABS == "present")
```

2)Subsetting commands

```
absent <- subset(salmon,  
  select = c("brook.trout.PRES.ABS",  
    "percent.surv"),  
  brook.trout.PRES.ABS == "absent")
```

```
> present  
  brook.trout.PRES.ABS percent.surv  
1                present      0.2024390  
2                present      0.1416667  
3                present      0.2185714  
4                present      0.1889908  
5                present      0.2249675  
6                present      0.1878122
```

3new Subset dataframes

```
> absent  
  brook.trout.PRES.ABS percent.surv  
7                absent      0.3854390  
8                absent      0.1856100  
9                absent      0.3168124  
10               absent      0.2592593  
11               absent      0.1202405  
12               absent      0.1442308
```
